# ON THE UNIVERSAL AND GENERALIZED ORBIFOLD EULER CHARACTERISTICS 

S.M. GUSEIN-ZADE, I. LUENGO, A. MELLE-HERNÁNDEZ, AND A. VIRUEL

#### Abstract

We discuss the universal orbifold Euler characteristic and generalized orbifold Euler characteristics corresponding to finitely generated groups $A$ (the $A$-Euler characteristics). We show that the collection of all $A$-Euler characteristics for $A$ of the form $A^{\prime} \times \mathbb{Z}$ with finite $A^{\prime}$ determine the universal orbifold Euler characteristic.

## 1. Introduction

In all the paper, $\chi(\cdot)$ denotes the additive Euler characteristic defined as the alternating sum of the ranks of the cohomology groups with compact support:

$$
\begin{equation*}
\chi(X)=\sum_{q \geq 0}(-1)^{q} \cdot \operatorname{rk} H_{c}^{q}(X ; \mathbb{Z}) \tag{1}
\end{equation*}
$$

The (classical) orbifold Euler characteristic was defined by physicists in [3] and [4] (and appeared in the mathematical literature in [1] and [11]). There were defined some generalizations of this notion. First, in [1] and [2], there were defined, so-called, higher order analogues of the orbifold Euler characteristic. Then, in [13] (see also [5], [6]), there were defined their generalizations corresponding to arbitrary (or, rather, almost arbitrary) finitely generated groups. (The higher order orbifoid Euler characteristics correspond to free abelian groups.) All of them were first defined for a manifold (or a topological space) with an action of a finite group. The fact that they are really invariants of of orbifolds is related with the, so-called, induction property: [10]. (A more simple

[^0]proof valid in a more restrictive setting (sufficient for this paper) can be found in [8, Theorem 1].)

In [9, there was defined the, so-called, universal orbifold Euler characteristic $\chi^{\mathrm{un}}(\cdot)$ which takes values in a certain ring $\mathcal{R}$ freely generated, as an abelian group, by the isomorphism classes of finite groups. It was shown that $\chi^{\mathrm{un}}$ is the universal additive topological invariant of orbifolds. This fact means, in particular, that the universal orbifold Euler characteristic determines all the generalized orbifold Euler characteristics corresponding to finitely generated groups.

There is a natural question, whether the generalized orbifold Euler characteristics carry the same information as the universal one. In other words, whether the generalized orbifold Euler characteristics corresponding to all finitely generated groups (or to finitely generated groups considered in [13]: see Section (3) determine the universal Euler characteristic.

In this paper we give the affirmative answer to this question. For that, we reduce the problem to a purely algebraic one and give a solution for the latter. The main statement of the paper is the following.
Theorem 1. The collection of the generalized orbifold Euler characteristics $\chi^{(A \times \mathbb{Z})}(X, G)$ corresponding to all the groups $A \times \mathbb{Z}$ with finite $A$ determines the universal orbifold Euler characteristic $\chi^{\mathrm{un}}(X, G)$.

This statement implies, in particular, that this collection of generalized orbifold Euler characteristics determines all other ones (corresponding to other finitely generated groups).

## 2. The universal orbifold Euler characteristic

The universal Euler characteristic of orbifolds (or, probably better to say, of spaces with actions of finite groups in the sense of [10]) was defined in [9].

Let $G$ be a finite group. For a topological $G$-space $X$ (nice enough, say, homeomorphic to a locally closed union of cells in a finite $G$-CWcomplex, see, e. g., [14]) and for a subgroup $K \subset G$, let $X^{K}$ be the fixed point set $\{x \in X: g x=x$ for all $g \in K\}$ of the subgroup $K$ and let $X^{(K)}$ be the set of points of $X$ whose isotropy subgroups $G_{x}=$ $\{g \in G: g x=x\}$ coincide with $K$. Let Conjsub $G$ be the set of the conjugacy classes of subgroups of $G$. For a class $[K] \in$ Conjsub $G$ (containing the subgroup $K$ ), let $X^{[K]}$ (respectively $X^{([K])}$ ) be the set of points of $X$ whose isotropy group contains a subgroup from the class $[K]$ (respectively, is a subgroup from $[K]$ ).

For a $G$-space $X$ and for a finite group $H \supset G$, let $\operatorname{Ind}_{G}^{H} X$ be the induced $H$-space defined in the following way. Let us consider the

Cartesian product $H \times X$ and let us say that two points $\left(h_{i}, x_{i}\right), i=1,2$, of it are equivalent if there exists $g \in G$ such that $h_{2}=h_{1} g, x_{2}=g^{-1} x_{1}$. Then $\operatorname{Ind}_{G}^{H} X$ is the quotient of $H \times X$ by this equivalence relation with the natural $H$-action: $h\left(h^{\prime}, x\right)=\left(h h^{\prime}, x\right)$. For finite groups $K \subset G \subset$ $H$, one has $\operatorname{Ind}_{K}^{H}=\operatorname{Ind}_{G}^{H} \circ \operatorname{Ind}_{K}^{G}$ and $\operatorname{Ind}_{G}^{H} G / K=H / K$.

The universal Euler characteristic of orbifolds takes values in the ring $\mathcal{R}$ which can be defined as the Grothendieck ring of finite sets ("zero-dimensional varieties") with actions of finite groups in the sense of [10]. This means the follwoing. Two finite sets $X_{1}$ and $X_{2}$ with actions of finite groups $G_{1}$ and $G_{2}$ respectively (that is a $G_{1}$-set $\left(X_{1}, G_{1}\right)$ and a $G_{2}$-set $\left.\left(X_{2}, G_{2}\right)\right)$ are called isomorphic if there exists a bijection $h: X_{1} \rightarrow X_{2}$ and a group isomorphism $\varphi: G_{1} \rightarrow G_{2}$ such that, for $x \in X_{1}$ and $g \in G_{1}$, one has $h(g x)=\varphi(g) h(x)$. Now $\mathcal{R}$ is the abelian group generated by the isomorphism classes $[(X, G)]$ of finite sets with actions of finite groups modulo the relations:

1) if $Y$ is a $G$-invariant subset of a $G$-set $X$, then $[(X, G)]=$ $[(Y, G)]+[(X \backslash Y, G)] ;$
2) if $G$ is a subgroup of a finite group $H$, then $[(X, G)]=\left[\left(\operatorname{Int}_{G}^{H} X, H\right)\right]$.

The multiplication in $\mathcal{R}$ is defined by the Cartesian product: $\left[\left(X_{1}, G_{1}\right)\right]$. $\left[\left(X_{2}, G_{2}\right)\right]=\left[\left(X_{1} \times X_{2}, G_{1} \times G_{2}\right)\right]$.

The ring $\mathcal{R}$ can be also described in the following way. Let $\mathcal{G}$ be the set of all isomorphisms classes of finite groups. Then $\mathcal{R}$ is the free Abelian group generated by the elements $T^{\mathcal{K}}$ corresponding to the classes $\mathcal{K} \in \mathcal{G}$. The element $T^{\mathcal{K}}$ is represented by the one-point $G$ set $G / G$ with $G \in \mathcal{K}: T^{\mathcal{K}}=[(G / G, G)]$. Thus an element of $\mathcal{R}$ can be written as a finite sum of the form $\sum_{\mathcal{K} \in \mathcal{G}} a_{\mathcal{K}} T^{\mathcal{K}}$, where $a_{\mathcal{K}} \in \mathbb{Z}$. The multiplication is defined by $T^{\mathcal{K}^{\prime}} \cdot T^{\mathcal{K}^{\prime \prime}}=T^{\left\{G^{\prime} \times G^{\prime \prime}\right\}}$ with $G^{\prime} \in \mathcal{K}^{\prime}$, $G^{\prime \prime} \in \mathcal{K}^{\prime \prime}$. According to the Krull-Schmidt theorem each finite group has a unique representation as the Cartesian product of indecomposable groups. Let $\mathcal{G}_{\text {ind }}$ be the set of the isomorphisms classes of indecomposable finite groups. The Krull-Schmidt theorem implies that $\mathcal{R}$ is the polynomial ring $\mathbb{Z}\left[T^{\mathcal{K}}\right]$ in the variables $T^{\mathcal{K}}$ corresponding to the isomorphisms classes of the indecomposable finite groups.

Definition 1. (cf. [9, Definition 7]) For a $G$-space $X$ ( $G$ is a finite group), the universal Euler characteristic is defined by:

$$
\begin{align*}
\chi^{\mathrm{un}}(X, G) & =\sum_{\mathcal{K} \in \mathcal{G}}\left(\sum_{\substack{[K] \in \operatorname{Conjsub} G \\
[K] \in \mathcal{K}}} \chi\left(X^{([K])} / G\right)\right) \cdot T^{\mathcal{K}} \\
& =\sum_{[K] \in \operatorname{Conjsub} G} \chi\left(X^{([K])} / G\right) \cdot T^{\{[K]\}}, \tag{2}
\end{align*}
$$

where $\{[K]\} \in \mathcal{G}$ is the isomorphism class of the groups from $[K]$.
The right-hand side of Equation (2) can be written as an integral with respect to the Euler characteristic:

$$
\chi^{\mathrm{un}}(X, G)=\int_{X / G} T^{\left\{G_{x}\right\}} d \chi
$$

where $\left\{G_{x}\right\}$ is the isomorphy class of the isotropy subgroup of a point from the orbit $G x$.

This definition can be extended to orbifolds (that is to spaces locally isomorphic to quotients $X / G)$. It is not difficult to see that $\chi^{\text {un }}$ is an additive and multiplicative invariant of $V$-manifolds. As it was mentioned in Introduction, $\chi^{\mathrm{un}}$ is a universal additive topological invariant of orbifolds.

## 3. Generalized orbifold Euler characteristics

The (classical) orbifold Euler characteristic was defined in [3] and (4] by the following two equivalent equations:

$$
\chi^{\operatorname{orb}}(X, G)=\frac{1}{|G|} \sum_{\substack{\left(g_{0}, g_{1}\right) \in G^{2} ; \\ g_{0} g_{1}=g_{1} g_{0}}} \chi\left(X^{\left\langle g_{0}, g_{1}\right\rangle}\right)=\sum_{[g] \in \operatorname{Conj} G} \chi\left(X^{\langle g\rangle} / C_{G}(g)\right),
$$

where $g$ is a representative of the class $[g], C_{G}(g)$ is the centralizer $\{h \in G: h g=g h\}$ of the element $g$ in $G$, and $\langle\ldots\rangle$ is the subgroup of $G$ generated by the corresponding elements. (A proof that these two equations are equivalent can be found in [11], see also [7, Proposition 6].)

For a $G$-space $X$, the higher order orbifold Euler characteristics were defined in [1] and [2] by the following equations
(3) $\chi^{(k)}(X, G)=\frac{1}{|G|} \sum_{\substack{\mathbf{g} \in G^{k+1 ;} \\ g_{i} g_{j}=g_{j} g_{i}}} \chi\left(X^{\langle\mathbf{g}\rangle}\right)=\sum_{[g] \in \operatorname{Conj} G} \chi^{(k-1)}\left(X^{\langle g\rangle}, C_{G}(g)\right)$,
where $k$ is a non-negative integer (the order of the Euler characteristic), $\mathbf{g}=\left(g_{0}, g_{1}, \ldots, g_{k}\right)$ and (for the second, recurrent, definition) $\chi^{(0)}(X, G)$ is given by the first definition and coincides with the Euler characteristic $\chi(X / G)$ of the quotient: see, e. g., [7, Proposition 7]. The usual orbifold Euler characteristic $\chi^{\text {orb }}(\cdot, \cdot)$ is the orbifold Euler characteristic of order 1. (One may include the Euler-Satake characteristic $\chi^{E S}(\cdot)$ (see [12]) into this series: the characteristic $\chi^{E S}(X, G)$ can be interpreted in a certain way as $\chi^{(-1)}(X, G)$.)

For a finitely generated group $A$, the (generalized) orbifold Euler characteristic corresponding to $A$ (or the $A$-Euler characteristic), is defined by

$$
\begin{equation*}
\chi^{(A)}(X, G)=\frac{1}{|G|} \sum_{\varphi \in \operatorname{Hom}(A, G)} \chi\left(X^{\varphi(A)}\right) \tag{4}
\end{equation*}
$$

where the summation is over the set of homomorphisms $\varphi: A \rightarrow G$, $X^{\varphi(A)}$ is the set of point of $X$ fixed with respect to all the elements of the image of $\varphi\left([13]\right.$, see also [5]). The value $\chi^{(A)}(X, G)$ is, in general, a rational number. In 13, the author considered only the generalized orbifold Euler characteristics corresponding to finitely generated groups of the form $A=\mathbb{Z} \times A^{\prime}$. An advantage of these class of the generalized orbifold Euler characteristics is that they take values in $\mathbb{Z}$ (see Proposition 11). Another advantage is the fact that there is a way to define "motivic versions" of them. This means that, for a complex quasiprojective $G$-variety $X$, one can define an element of the Grothendieck ring $K_{0}\left(\operatorname{Var}_{\mathbb{C}}\right)$ of complex quasiprojective varieties whose Euler characteristic is equal to $\chi^{(A)}(X, G)$.

It is not difficult to see that, for the trivial group $G$ (i.e., $G=\{e\}$ ) the $A$-Euler characteristic $\chi^{(A)}(X,\{e\})$ coincides with the usual Euler characteristic $\chi(X)$. The definition directly implies the additivity and the multiplicativity of the $A$-Euler characteristic in the following sense: if $X_{1}$ is a $G$-invariant subset of a $G$ space $X, X_{2}=X \backslash X_{1}$, then $\chi^{(A)}(X, G)=\chi^{(A)}\left(X_{1}, G\right)+\chi^{(A)}\left(X_{2}, G\right)$; if $X_{1}$ is a $G_{1}$-space and $X_{2}$ is a $G_{2}$-space, then

$$
\begin{equation*}
\chi^{(A)}\left(X_{1} \times X_{2}, G_{1} \times G_{2}\right)=\chi^{(A)}\left(X_{1}, G_{1}\right) \cdot \chi^{(A)}\left(X_{2}, G_{2}\right) \tag{5}
\end{equation*}
$$

Proposition 1. ([13, Proposition 2-1]) If $A=A_{1} \times A_{2}$, then

$$
\begin{equation*}
\chi^{(A)}(X, G)=\sum_{[\varphi] \in \operatorname{Hom}\left(A_{1}, G\right) / G} \chi^{\left(A_{2}\right)}\left(X^{\varphi\left(A_{1}\right)}, C_{G}\left(\varphi\left(A_{1}\right)\right)\right) \tag{6}
\end{equation*}
$$

where the group $G$ acts on the set $\operatorname{Hom}\left(A_{1}, G\right)$ by conjugation, $\varphi$ is a representative of the conjugacy class $[\varphi]$.

Proof. (cf. the proofs of [13, Proposition 2-1] and [7, Proposition 6]) One has:

$$
\begin{aligned}
& \chi^{(A)}(X, G)=\frac{1}{|G|} \sum_{\varphi \in \operatorname{Hom}(A, G)} \chi\left(X^{\varphi(A)}\right) \\
= & \frac{1}{|G|} \sum_{[\varphi] \in \operatorname{Hom}\left(A_{1}, G\right) / G} \sum_{\psi \in \operatorname{Hom}\left(A_{2}, C_{G}\left(\varphi\left(A_{1}\right)\right)\right)} \chi\left(X^{\varphi\left(A_{1}\right) \cdot \psi\left(A_{2}\right)}\right) \\
= & \frac{1}{|G|} \sum_{[\varphi] \in \operatorname{Hom}\left(A_{1}, G\right)} \frac{|G|}{\left|C_{G}\left(\varphi\left(A_{1}\right)\right)\right|} \sum_{\psi \in \operatorname{Hom}\left(A_{2}, C_{G}\left(\varphi\left(A_{1}\right)\right)\right)} \chi\left(\left(X^{\left.\left.\varphi\left(A_{1}\right)\right)^{\psi\left(A_{2}\right)}\right)}\right.\right. \\
= & \sum_{[\varphi] \in \operatorname{Hom}\left(A_{1}, G\right) / G} \chi^{\left(A_{2}\right)\left(X^{\varphi\left(A_{1}\right)}, C_{G}\left(\varphi\left(A_{1}\right)\right)\right) .}
\end{aligned}
$$

## 4. Reduction to a group theoretic problem

One can consider the $A$-Euler characteristic as a function on the ring $\mathcal{R}$, defining $\chi^{(A)}([X, G])\left(X\right.$ is a finite $G$-set) as $\chi^{(A)}(X, G)$, where $X$ is considered as a zero-dimensional topological space (with the discrete topology). The fact that this function is well-defined is a consequence of the following induction property. (It was proved first for the higher order orbifold Euler characteristics in [10, Theorem 1]. See a more simple proof for an arbitrary finitely generated group $A$ (in a purely topological setting) in [8, Theorem 1].)

Proposition 2. Let $G \subset H$ be finite groups. For a $G$-space $X$ one has

$$
\chi^{(A)}(X, G)=\chi^{(A)}\left(\operatorname{Ind}_{G}^{H} X, H\right)
$$

From the definition of the universal Euler characteristic, it follows that

$$
\chi^{(A)}(X, G)=\chi^{(A)}\left(\chi^{\mathrm{un}}(X, G)\right)
$$

Now let $\mathcal{A}$ be a set of finitely generated groups (considered up to isomorphisms). The fact that the generalized orbifold Euler characteristics $\chi^{(A)}$ for $A \in \mathcal{A}$ define the universal Euler characteristic $\chi^{\mathrm{un}}$ is equivalent to the fact that their common kernel in $\mathcal{R}$ is trivial, i. e., if $\chi^{(A)}(r)=0$ for all $A \in \mathcal{A}(r \in \mathcal{R})$, then $r=0$.

We shall show that this is the case for $\mathcal{A}$ being the set of groups $A$ of the form $A=A^{\prime} \times \mathbb{Z}$ with finite $A^{\prime}$. For that we have to compute $\chi^{(A)}(r)$ for a finite sum $r=\sum_{\mathcal{K} \in \mathcal{G}} a_{\mathcal{K}} T^{\mathcal{K}}\left(a_{\mathcal{K}} \in \mathbb{Z}\right)$. The following statement gives the answer for $A=A^{\prime} \times \mathbb{Z}$.

Proposition 3. One has

$$
\chi^{\left(A^{\prime} \times \mathbb{Z}\right)}(G / G, G)=\left|\operatorname{Hom}\left(A^{\prime}, G\right) / G\right|
$$

Proof. Proposition 1 applied to $A_{1}=A^{\prime}, A_{2}=\mathbb{Z}$ gives

$$
\chi^{\left(A^{\prime} \times \mathbb{Z}\right)}(G / G, G)=\sum_{\varphi \in \operatorname{Hom}\left(A^{\prime}, \mathrm{G}\right) / \mathrm{G}} \chi^{(\mathbb{Z})}\left((G / G)^{\varphi\left(A^{\prime}\right)}, C_{G}\left(\varphi\left(A^{\prime}\right)\right)\right)
$$

On the other hand, $\chi^{(\mathbb{Z})}(Y, H)=\chi(Y / H)$ and $(G / G)^{\varphi\left(A^{\prime}\right)}$ is the onepoint set. Therefore, $\chi^{(\mathbb{Z})}\left((G / G)^{\varphi\left(A^{\prime}\right)}, C_{G}\left(\varphi\left(A^{\prime}\right)\right)\right)=1$.

This gives the following criterion for the $A$-Euler characteristics for $A$ of the form $A^{\prime} \times \mathbb{Z}$ (with $A^{\prime}$ finite) to define the universal orbifold Euler characteristic: if, for $a_{\mathcal{K}} \in \mathbb{Z}$ such that finitely many of them are different from zero and for any finite group $A^{\prime}$, one has

$$
\sum_{\mathcal{K} \in \mathcal{G}} a_{\mathcal{K}}\left|\operatorname{Hom}\left(A^{\prime}, G\right) / G\right|=0
$$

( $G$ is a representative of $\mathcal{K}$ ), then all $a_{\mathcal{K}}$ are equal to zero. This will be proved in Section 5: Theorem 2.
Remark. It is somewhat easier to prove that the $A$-orbifold Euler characteristics for all finitely generated groups $A$ determine the universal orbifold Euler characteristic. This can be deduced from the statement that, for any two non-isomorphic finite groups $G_{1}$ and $G_{2}$, there exists a finite group $A$ such that $\left|\operatorname{Hom}\left(A^{\prime}, G_{1}\right) / G_{1}\right| \neq\left|\operatorname{Hom}\left(A^{\prime}, G_{2}\right) / G_{2}\right|$ (a very particular case of Theorem 2 below).

## 5. Counting morphisms Between finite groups

We shall prove some statements in a somewhat more general setting than it is necessary for the described aim of the paper. In what follows, for every given group $G$, we chose a fixed subgroup $\omega(G)$ of $\operatorname{Aut}(G)$. The assignation $\omega$ is not required to fulfill any other extra hypothesis; it needs not to be functorial or consistent within any class of groups.

Now, if $A, B$ are groups, then there is a left-action of $\operatorname{Aut}(B)$ on the set $\operatorname{Hom}(A, B)$ given by post-composition, thus a left $\omega(B)$-action as well.

Definition 2. Let $A, B$ be groups, then
(1) The set of $\omega$-representations of $A$ in $B$ is the set of $\omega(B)$-orbits:

$$
\operatorname{Rep}_{\omega}(A, B):=\omega(B) \backslash \operatorname{Hom}(A, B) .
$$

(2) The set of faithful $\omega$-representations of $A$ in $B$ is the set of $\omega(B)$-orbits:

$$
\operatorname{FRep}_{\omega}(A, B):=\omega(B) \backslash \operatorname{Mono}(A, B)
$$

Lemma 1. Let $A, B$ be groups, then

$$
\operatorname{Rep}_{\omega}(A, B)=\bigsqcup_{K \unlhd A} \operatorname{FRep}_{\omega}(A / K, B)
$$

Proof. Notice that every group morphism $f: A \rightarrow B$ factors in a unique way as

where $\bar{f}$ is a monomorphism. In other words, every group morphism $f: A \rightarrow B$ is completely determined by the pair $(\operatorname{ker}(f), \bar{f})$ where $\operatorname{ker}(f) \unlhd A$ and $\bar{f}: A / \operatorname{ker}(f) \rightarrow B$ is a monomorphism. And given any pair $(K, \bar{f})$, where $K \unlhd A$ and $\bar{f}: A / K \rightarrow B$ is a monomorphism, there exists a unique group morphism $f: A \rightarrow B$ determined by the composition

$$
A \xrightarrow{p} A / K \xrightarrow{\bar{f}} B .
$$

Hence

$$
\begin{equation*}
\operatorname{Hom}(A, B)=\bigsqcup_{K \unlhd A} \operatorname{Mono}(A / K, B) \tag{7}
\end{equation*}
$$

Finally, the $\omega(B)$-action on $\operatorname{Hom}(A, B)$ is via post-composition, and therefore, given a pair $(K, \bar{f})$ the $\omega(B)$-action only applies to $\bar{f}$. Indeed, if $\theta \in \omega(B)$ and $f \in \operatorname{Hom}(A, B)$ then $\operatorname{ker}(f)=\operatorname{ker}(\theta \circ f)$, hence the orbit $[f] \in \operatorname{Rep}_{\omega}(A, B)$ is fully determined by the pair $(\operatorname{ker}(f),[\bar{f}])$ where $\operatorname{ker}(f)$ does not depend on the representative of the $\omega(B)$-orbit $[f]$, and $[\bar{f}] \in \operatorname{FRep}_{\omega}(A / \operatorname{ker}(f), B)$. Therefore, the $\omega(B)$-action on $\operatorname{Hom}(A, B)$ is compatible with the decomposition given by Equation (7), and the result follows.

A straightforward consequence of Lemma 1 is the following:
Corollary. Let $A, B$ be finite groups, then

$$
\left|\operatorname{Rep}_{\omega}(A, B)\right|=\sum_{K \unlhd A}\left|\operatorname{FRep}_{\omega}(A / K, B)\right|
$$

Remark. Note that the assumption of finiteness for both $A$ and $B$ is solely to ensure that the sum on the right-hand side of the formula makes sense.

The following result shows that considering linear combinations involving the size of $\omega$-representation is equivalent to consider linear combinations involving the size of faithful $\omega$-representation.

Lemma 2. Let $R$ be a ring, $a_{1}, \ldots, a_{r} \in R$, and $G_{1}, \ldots, G_{r}$ be finite groups. Then the following are equivalent:
(1) For every finite group $A$, the following equation holds:

$$
\sum_{i=1}^{s} a_{i}\left|\operatorname{Rep}_{\omega}\left(A, G_{i}\right)\right|=0
$$

(2) For every finite group $A$, the following equation holds:

$$
\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A, G_{i}\right)\right|=0
$$

Proof. First assume (2). Then, according to Lemma 1;

$$
\begin{aligned}
\sum_{i=1}^{s} a_{i}\left|\operatorname{Rep}_{\omega}\left(A, G_{i}\right)\right| & =\sum_{i=1}^{s} a_{i}\left(\sum_{K \unlhd A}\left|\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)\right|\right) \\
& =\sum_{K \unlhd A}\left(\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)\right|\right) \\
& =0,
\end{aligned}
$$

hence (1) follows.
Now, we assume (1), and prove that (2) follows by an inductive argument on $|A|$.

If $|A|=1$, then $A$ is the trivial group and $\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)=$ $\operatorname{Rep}_{\omega}\left(A / K, G_{i}\right)$ for every $i$, hence there is nothing to prove.

Assume now that (11) holds for every finite group of size smaller that $n$, and let $A$ be a group with $|A|=n$. Then, according to Lemma 1 :

$$
\begin{aligned}
0 & =\quad \sum_{i=1}^{s} a_{i}\left|\operatorname{Rep}_{\omega}\left(A, G_{i}\right)\right|=\sum_{i=1}^{s} a_{i}\left(\sum_{K \unlhd A}\left|\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)\right|\right) \\
& =\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A, G_{i}\right)\right|+\sum_{\{1\} \neq K \unlhd A}\left(\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)\right|\right),
\end{aligned}
$$

where if $\{1\} \neq K \unlhd A$ then $|A / K|<n$ and $\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A / K, G_{i}\right)\right|=$ 0 by the induction hypothesis. Hence (21) holds for $A$ too.

Now our main result in this section.

Theorem 2. Let $R$ be a ring and $\left\{G_{1}, \ldots, G_{s}\right\}$ be a finite set of pairwise non-isomorphic finite groups such that $\left|\operatorname{FRep}_{\omega}\left(G_{i}, G_{i}\right)\right|$ is not a zero divisor in $R, i=1, \ldots, s$. If $a_{1}, \ldots, a_{s} \in R$ are such that for every finite group $A$ the equation

$$
\sum_{i=1}^{s} a_{i}\left|\operatorname{Rep}_{\omega}\left(A, G_{i}\right)\right|=0
$$

holds, then $a_{i}=0$ for $i=1, \ldots, s$.
Proof. According to Lemma 2, we may assume that for every finite group $A$ the equation

$$
\begin{equation*}
\sum_{i=1}^{s} a_{i}\left|\operatorname{FRep}_{\omega}\left(A, G_{i}\right)\right|=0 \tag{8}
\end{equation*}
$$

holds.
We may also assume that the finite groups have been ordered so that

$$
\left|G_{1}\right| \leq\left|G_{2}\right| \leq \ldots \leq\left|G_{s}\right|
$$

and since the groups $G_{i}$ are pairwise non-isomorphic, this implies

$$
\left|\operatorname{FRep}_{\omega}\left(G_{j}, G_{i}\right)\right|=0 \text { for } j<i
$$

Now, if $A=G_{s}$ then Equation (8) gives rise to

$$
a_{s}\left|\operatorname{FRep}_{\omega}\left(G_{s}, G_{s}\right)\right|=0
$$

and since $\left|\operatorname{FRep}_{\omega}\left(G_{s}, G_{s}\right)\right|$ is not a zero divisor in $R$, this implies $a_{s}=0$. So we can assume now that we are dealing with just $s-1$ pairwise nonisomorphic finite groups, and iterate this process to end that $0=a_{s}=$ $a_{s-1}=\ldots=a_{1}$.

Now Theorem 1 follows from Theorem 2 applied to $w(G)$ being the group of inner automorphisms of $G($ and $R=\mathbb{Z})$.

Theorem 3. The collection of the generalized orbifold Euler characteristics $\chi^{(A \times \mathbb{Z})}(X, G)$ corresponding to all the groups $A \times \mathbb{Z}$ with finite $A$ determines the universal orbifold Euler characteristic $\chi^{\mathrm{un}}(X, G)$.

This statement implies, in particular, that this collection of generalized orbifold Euler characteristics determines all other ones (corresponding to other finitely generated groups).
